1 **Abstract:**

2 **Purpose:** To identify the association between ABO blood type and the survival of nasopharyngeal carcinoma patients.

3 **Patients and methods:** We retrospectively analyzed 2439 consecutive non-metastasis nasopharyngeal carcinoma  
4 patients between January 2001 and December 2004 at the Sun Yat-sen University Cancer Center. Survival outcomes  
5 were compared using Kaplan-Meier method. Univariate and multivariate analysis was performed by Cox regression  
6 model. Chi-square test was performed to compare categorical variables.

7 **Results:** In the whole patients, compared with non-O blood type (A, B, and AB) patients, type O patients had  
8 significantly lower 5-year distant metastasis-free survival (DMFS) (adjusted hazard ratio (aHR)= 1.268, 95% CI 1.010-  
9 1.592, P=0.041). Moreover, we observed in female patients, O blood type patients had significantly lower 5-year  
10 overall survival(OS), disease-specific survival(DSS) and distant metastasis-free survival (DMFS) than those with non-O  
11 blood type (aHR=1.495, 95% CI 1.032-2.165, P=0.034 for OS; aHR=1.566, 95% CI 1.054-2.328, P=0.026 for DSS;  
12 aHR=1.779, 95% CI 1.056-2.998, P=0.030 for DMFS). In male patients, there was no significant difference observed  
13 between O blood type patients and non-O blood type patients in any survival endpoints.

14 **Conclusion:** O blood type is associated with an unfavorable DMFS in female patients with nasopharyngeal carcinoma  
15 in epidemic area, which contributes to unfavorable OS and DSS in female patients, even contributes to a lower DMFS  
16 in the whole patients. It might be beneficial to predict metastasis so as to guide the treatment in female patients with  
17 nasopharyngeal carcinoma in epidemic area.

18 **Key words:** Nasopharyngeal carcinoma; Blood type; Female patients; Distant-metastasis-free survival.

## 1 **Introduction**

2 Nasopharyngeal carcinoma (NPC), arises from the nasopharyngeal epithelium[1]. Worldwide, 86,500 cases of  
3 NPC were reported in 2012, with 71% of all new cases in east and Southeast Asia, with China contributing 53.5%  
4 of these cases[2, 3]. Several factors have been proved to enhance the risk of NPC, smoking, alcohol consumption,  
5 and family history of cancer and so on[4-6].

6 The ABO gene, located on chromosome 9q34.1 to 9q34.2, encodes a specific glycosyl transferase that  
7 synthesizes A and B agglutinogens to form the ABO blood type agglutinogens[7], expressed by erythrocytes,  
8 most epithelial cells, endothelial cells and so on[8]. Relationship between the ABO blood type and prognosis  
9 have been reported in many tumor types, such as leukemia[9], pancreatic cancer[10-12], bladder cancer[13],  
10 gastric cancer[14-16], renal cell carcinoma [17], breast cancer[18,19], lung cancer[20,21]and so on.

11 The correlation between ABO blood type and NPC remains controversial. Some researches demonstrated  
12 the absence of an association between ABO blood type and NPC[22-24]. Other studies indicated that the ABO  
13 blood type was related to NPC susceptibility, for instance A blood type increased risks, mainly in male  
14 patients[25-27].

15 Therefore, we sought to conduct a study to assess the prognostic value of different blood types in NPC  
16 patients, to determine whether certain blood type is an independent predictor of prognosis so as to guide the  
17 clinical practice.

## 18 **Material and methods**

### 19 **Population**

20 We reviewed all the 2,626 patients who were newly diagnosed with NPC without distant metastasis between  
21 January 2001 and December 2004 at the Sun Yat-sen University Cancer Center (SYSUCC). We collected data on  
22 basic characteristics including age, gender, tumor family history, cigarette smoking status at diagnosis, alcohol  
23 drinking status at diagnosis, BMI status at diagnosis, whether to receive chemotherapy and ABO blood type. 187  
24 patients with missing data were excluded from this study. All cases were restaged according to the 7th edition of  
25 the UICC/AJCC staging system[28]. Computed tomography and/or magnetic resonance imaging was essential for  
26 disease staging before treatment, and all patients were treated by CRT(n=2287), or IMRT(n=152) with or  
27 without chemotherapy. For 2D-CRT, high energy 6-8 MV X-ray of linear accelerator was used. The radiation field

1 included the skull base, nasopharynx and neck. Face-neck joint field and lower cervical anterior tangent field  
2 were irradiated to a dose of 36 Gy, and then followed by bilateral preauricular fields plus anterior tangent field  
3 to a total dose of 60 to 78 Gy. For IMRT, simultaneous integrated boost (SIB) technique was used. All patients  
4 were scanned with serial 3-mm slices from the vertex through the clavicles in supine position with a head, neck,  
5 and shoulder thermoplastic mask. GTV was defined as the primary nasopharyngeal gross tumor volume and the  
6 involved cervical lymph nodes and was prescribed 66-70Gy in 30-32 fraction. CTV1 was defined as the GTVnx  
7 plus a margin of 5–10 mm for potential microscopic spread and was prescribed 60Gy in 30-32 fractions. CTV2  
8 was defined by adding a margin of 5–10 mm to CTV1 (reduced when adjacent critical organ at risk (OAR)) and  
9 included the retropharyngeal lymph nodal regions, clivus, skull base, pterygoid fossae, parapharyngeal space,  
10 inferior sphenoid sinus, and posterior edge of the nasal cavity and maxillary sinuses, and was prescribed 54Gy  
11 in 30-32 fractions. For N0 patients, lower neck was not irradiated. While for N positive patients, the whole neck  
12 was delineated in CTV2. Chemotherapy included induction chemotherapy, concomitant chemotherapy, and  
13 adjuvant chemotherapy. Chemotherapy regimen was mainly based on platinum.

#### 14 **Study design**

15 The flowchart of study design is shown in Figure 1. We first analyzed the endpoints including overall survival  
16 (OS), disease-specific survival (DSS), locoregional relapse-free survival (LRFS) and distant metastasis-free  
17 survival (DMFS) among all the 4 ABO blood types pairwise over strata in the whole 2439 patients to select  
18 certain blood type with prognostic value. Then, we further compared certain blood type patients with others in  
19 the whole 2439 patients, 559 female patients and 1880 male patients respectively.

#### 20 **Endpoints**

21 Overall survival (OS) time was defined as time from diagnosis to death from any cause. Disease-specific survival  
22 (DSS) time was defined in this analysis as the percentage of patients of a dataset who did not die from NPC in a  
23 defined period of time. Locoregional recurrent free survival (LRFS) time was defined as time to the first  
24 occurrence of tumor growth at the primary site or regional lymph nodes and death from the primary cancer  
25 without a documented site of recurrence or metastasis. Distant metastasis free survival (DMFS) time was  
26 defined as time to the first occurrence of distant failure during follow-up.

#### 27 **Statistical analysis**

1 Analyses were performed using SPSS software, version 24.0. The Chi-square test was used to compare  
2 categorical variables. Survival rates were estimated by means of life table method. Cox proportional hazards  
3 model was used to test the independent significance of different variables by backward elimination. Receiver  
4 operating characteristic (ROC) curve analysis was used to evaluate the predicted validity of age, based on the  
5 method of Hanley and McNeil[29]. Kaplan-Meier survival curve figures were performed by GraphPad Prism  
6 software, version 6.04.

## 7 **Results**

### 8 **Baseline characteristics**

9 The clinical characteristics of the 2439 patients are shown in Table 1. The proportions of O, A, B, and AB blood  
10 types were: 40.1 % (977/2439), 26.3% (641/2439), 27.5% (670/2439) and 6.2% (151/2439) respectively.  
11 There were no significant difference observed between O blood group patients and non-O blood group patients.  
12 According to the ROC curve analysis based on OS, the optimal age cut-off value was 53 years (area under curve:  
13 0.592; sensitivity, 0.547; specificity, 0.471) for the 2439 patients. The 5-year survival rates for the 2439 patients  
14 were 76.3%, 79.2%, 85.7%, and 87.7% for OS, DSS, LRFS, and DMFS, respectively.

### 15 **Selection of certain blood type with prognostic value in the whole patients**

16 We analyzed all endpoints among all the 4 ABO blood types pairwise over strata in the whole patients. There  
17 was almost no significant difference between any pair blood group, except for DMFS between B blood type  
18 patients, O blood type patients (Table 2). Compared with B blood type patients, O blood type patients had lower  
19 DMFS (hazard ratio (HR)=1.410, 95% CI 1.052-1.889, P=0.021 in univariate analysis; adjusted hazard ratio  
20 (aHR)=1.411, 95% CI 1.053-1.891, P=0.021 in multivariate analysis). Therefore, we confined A, B and AB blood  
21 type patients undifferentiated and collected them together into non-O blood type patients, so as to further  
22 compare with O blood type patients. Similarly, there was almost no significant difference between O and non-O  
23 blood type patients, except that O blood type patients had significant lower DMFS than non-O blood type  
24 patients (HR=1.262, 95% CI 1.006-1.584, P=0.045 in univariate analysis; aHR=1.268, 95% CI 1.010-1.592,  
25 P=0.041 in multivariate analysis; Table 3, Figure 2A).

### 26 **Prognostic value of O blood type in female patients**

1 In female patients, compared with non-O blood type patients, O blood type patients had significant lower OS, DSS  
2 and DMFS in univariate analysis (HR=1.471, 95% CI 1.016-2.131, P=0.041 for OS; HR=1.534, 95% CI 1.032-2.279,  
3 P=0.034 for DSS; HR=1.748, 95% CI 1.038-2.943, P=0.036 for DMFS), and in multivariate analysis (aHR=1.495,  
4 95% CI 1.032-2.165, P=0.034 for OS; aHR=1.566, 95% CI 1.054-2.328, P=0.026 for DSS; aHR=1.779, 95% CI  
5 1.056-2.998, P=0.030 for DMFS). There was no significant difference in LRFS observed (aHR=1.237, 95% CI  
6 0.738-2.074, P=0.419; Table 3, Figure 2B, Figure 3).

### 7 **Prognostic value of O blood type in male patients**

8 In male patients, there were no significant differences observed between O blood type patients and non-O blood  
9 type patients in OS, DSS, LRFS and DMFS (P>0.05 for all rates; Table 3, Figure 2C).

## 10 **Discussion**

11 In the whole patients, compared with non-O blood type (A, B, and AB) patients, type O patients had significantly  
12 lower 5-year distant metastasis-free survival (Table 3, Figure 2A). Furthermore, in female patients, O blood type  
13 patients didn't only have significantly lower DMFS but also lower OS, DSS than patients with non-O blood type,  
14 except LRFS (Table 3, Figure 2B). However, none of them was observed in male patients (Table 3, Figure  
15 2C). Therefore, we deduced that female NPC patients with O blood type might have lower DMFS, which resulted  
16 in lower OS and DSS compared with those with non-O blood type, even dragged down DMFS in the whole NPC  
17 population.

18 Previous studies have evaluated the association of ABO blood types with NPC[22-27]. The two studies by  
19 Sheng et al[25] and Ouyang et al[26] revealed that patients with A blood type had significantly lower OS and  
20 DMFS compared to patients with non-A blood type. Therefore, the failure patterns were mainly compared  
21 between A and other blood type patients to clarify the differences. However, when we set A blood type as the  
22 control group, the results showed no association of ABO blood types with NPC (Figure 4, Figure 5).

23 In subgroup analysis by Ouyang et al[26], the increased risks of OS and DMFS associated with A blood type  
24 were only observed in male patients, which was attributed to unbalanced gender distribution between the  
25 patients with blood type A and non-A blood types. However, the results of our subgroup analysis showed A  
26 blood type patients had similar prognosis with others, whether in male patients or not (Figure 6; Figure 7). It  
27 should be pointed out that patients in our study made up a consecutive cohort, which included several

1 pathological types, radiotherapy techniques and other features, so as to decrease some bias compared with  
2 selected cohort studied in other studies. So these results may help to further confirm that A blood type may have  
3 no prognostic value in NPC. Peng et al[24] showed that ABO blood type was not an independent prognostic  
4 factor for DFS, OS, DMFS or LRFS after adjusting for plasma EBV-DNA. There might be some prognostic value in  
5 ABO blood type but offset by adjusting for plasma EBV-DNA. Moreover, it used the four-year survival endpoints  
6 to analyze, might get the misleading conclusion resulting from insufficient follow-up time.

7       Aside from NPC, ABO blood types have been reported associated with prognosis in various kinds of tumors  
8 [10-21]. For instance, A blood type is associated with risk of gastric cancer[14,15], attributed to A blood type  
9 alleles affected the fucosyltransferase enzymes which are involved in Lewis antigen formation known to be  
10 important factors in H. pylori adhesion and infection identified by phenotype analysis[16]. Likewise, A blood type  
11 is associated with unfavorable survivals in some other tumors, such as breast cancer[18,19], lung cancer[20,21]  
12 and so on. O blood type is associated with a reduced risk of pancreatic cancer[10-12]. Which might be attributed  
13 to ABO blood group IgM isoagglutinins interact with tumor-associated O-glycan structures in pancreatic  
14 cancer[12]. Similarly, non-O blood type was significantly associated with decreased OS in renal cell carcinoma  
15 patients[17]. Conversely, O blood type is associated with the worst recurrence and progression rates in  
16 nonmuscle invasive bladder cancer[13].

17       The mechanism of how ABO blood type may influence NPC progression remains relatively elusive.  
18 Underlying molecular and pathogenic differences may play important roles in the effect of ABO blood types on  
19 survival. Firstly, ABO gene is located on chromosome 9q34, which is a common region of loss in NPC[30].  
20 Secondly, a study in women showed an association between ABO blood group status and the serum levels of  
21 soluble intercellular adhesion molecule-1 (sICAM-1)[31]. The sICAM-1 concentration is higher in women with O  
22 blood type, particularly higher than those with A blood type. In addition, the higher serum sICAM-1  
23 concentration is related to the worse survival in NPC[32]. Neoplastic transformation and evolution to metastatic  
24 disease are characterized by a dramatic aberration in cellular cohesive interaction. The adhesion molecules have  
25 also been shown to facilitate tumor cell mobility, adhesion of tumor cells to endothelium, neovascularization at  
26 the metastatic sites, and host inflammatory response to cancer[33,34]. Intercellular adhesion molecule 1 is an  
27 inducible cell-surface adhesion molecule, and the ICAM-1/LFA-1 pathway plays a major role in a variety of  
28 cell-mediated immune responses. It has been reported that ICAM-1 on the surface of cancer cells or antigen-

1 presenting cells (ie,macrophages) is a costimulatory factor that stabilizes T-cell receptor-mediated binding  
2 between these cells and T lymphocytes[35]. Soluble ICAM-1 would work as an immunosuppressive agent by  
3 blocking LFA-1 on T lymphocytes, thus rendering it less available for binding with cell-surface ICAM-1 on cancer  
4 cells[36]. In this manner, the shedding of sICAM-1 may enhance the metastatic process by escaping host immune  
5 surveillance. This process therefore represents an additional potential mechanism for high serum levels of  
6 sICAM-1 in patients with NPC that has metastasized via hematogenous and lymphatic routes.So the higher  
7 concentration of sICAM-1 in O blood type patients, may partially explain the poorer survival of O blood type NPC  
8 patients. Thirdly, the expression change of serum tumour necrosis factor-alpha (sTNF-a) level is closely related  
9 to tumour progression and prognosis in many cancers including NPC[36-38]. It is well established that separate  
10 genotyping of SNP accurately recode individuals with their ABO blood group based on a two SNP haplotype  
11 (rs8176746 and rs8176719). Individuals of blood group O had TNF-alpha levels higher than others[39]. While,  
12 high expression levels of sTNF-a predict bone invasion, post-treatment distant metastasis and poor overall  
13 survival in NPC patients[40]. Further basic researches about NPC genetic, biological differences associated with  
14 the ABO blood types are required. Therefore, our next research direction will be for these underlying  
15 machanisms for further exploration and validation.

16 The limitations of our study are related to its retrospective nature. We were unable to collect adequate  
17 information regarding the patients' pretreatment plasma EBV-DNA copy number, which has been demonstrated  
18 to strongly predict survival[28]. We excluded patients with missing data, such as with unknown ABO blood type.  
19 Finally, 233/2439 (11.9%) patients for the entire population, 124/977 (12.7%) and 166/1462 (11.4%) patients  
20 with O and non-O blood type were lost to follow up, respectively.

## 21 **Conclusion**

22 O blood type is associated with an unfavorable DMFS in female patients with nasopharyngeal carcinoma in  
23 epidemic area, which contributes to unfavorable OS and DSS in female patients, even contributes to a lower  
24 DMFS in the whole patients. It might be beneficial to predict metastasis so as to guide the treatment in female  
25 patients with nasopharyngeal carcinoma in epidemic area.
